

60. Half reaction 1: $\text{Br}_2(\text{l}) + 2\text{e}^- = 2\text{Br}^-$: $E_0 = 1.07 \text{ V}$

Half reaction 2: $\text{Al}^{3+} + 3\text{e}^- = \text{Al}(\text{s})$: $E_0 = -1.66 \text{ V}$

Half reaction 1 has a higher E_0 , so that is the reduction half-reaction, and the reverse of half reaction 2 is the oxidation half-reaction. Oxidation occurs at the anode, which is written first in line notation:

$\text{Al}(\text{s}) \mid \text{Al}^{3+}(\text{aq}, 0.10\text{M}) \parallel \text{Br}^-(\text{aq}, 0.10\text{M}) \mid \text{Br}_2(\text{l}) \mid \text{Pt}(\text{s})$

For evaluating the cell potential, we take the sum of the half reactions to get E_0 at standard conditions, which is $1.07\text{V} + 1.66\text{V} = 2.73\text{V}$. To evaluate at 25°C , we use the Nernst Equation after obtaining the balanced chemical equation of $2\text{Al}(\text{s}) + 3\text{Br}_2(\text{l}) = 2\text{Al}^{3+} + 6\text{Br}^-$, then getting a reaction quotient $Q = [\text{Al}^{3+}]^2 [\text{Br}^-]^6 = [0.10]^8 = 10^{-8}$. $E = E_0 - 0.0591/n \times \log Q = 2.73 - 0.0591/6 \times \log(10^{-8}) = 2.81 \text{ V}$, which is galvanic because it is positive.

61. $\text{Pt}(\text{s}) \mid \text{Pb}(\text{s}), \text{PbCl}_2(\text{s}) \mid \text{Cl}^-(\text{aq}) \parallel \text{Pb}^{2+}(\text{aq}) \mid \text{Pb}(\text{s}), \text{Pt}(\text{s})$

The two half reactions are $\text{Pb}^{2+} + 2\text{e}^- = \text{Pb}$ and $\text{Pb} + 2\text{Cl}^- = \text{PbCl}_2 + 2\text{e}^-$, which are the reduction and oxidation respectively. $E_0 = -0.13 + 0.27 = 0.14$. To find the solubility product, we find the ion product assuming equilibrium, which means we can plug values into the Nernst Equation and solve for Q , which in this case is the reciprocal of the ion product since the ions are reactants for the reaction. $0 = 0.14 - 0.0591/2 \times \log(1/K_{\text{sp}}) \Rightarrow K_{\text{sp}} = 1.85 \times 10^{-5}$

68. $\text{Au} \mid \text{Fe}^{2+}(\text{aq}, 0.1 \text{ M}), \text{Fe}^{3+}(\text{aq}, 0.1 \text{ M}) \parallel \text{Mn}^{2+}(0.1\text{M}, \text{aq}), \text{MnO}_4^-(\text{aq}, 0.1\text{M}), \text{H}^+(\text{aq}, 0.1 \text{ M}) \mid \text{Au}$

Half reaction 1: $\text{Fe}^{3+} + \text{e}^- = \text{Fe}^{2+}$, $E_0 = 0.77 \text{ V}$

Half reaction 2: $\text{MnO}_4^- + 8\text{H}^+ + 5\text{e}^- = \text{Mn}^{2+} + 4\text{H}_2\text{O}$, $E_0 = 1.51 \text{ V}$.

Half reaction 2 is the reduction, and half reaction 1 is the oxidation.

$E_0 = 1.51 \text{ V} - 0.77 \text{ V} = 0.74 \text{ V}$

Multiplying the first reaction through by 5 gets both half reactions to an n of 5, so they can be added. This yields a reaction of $5\text{Fe}^{2+} + \text{MnO}_4^- + 8\text{H}^+ \rightarrow 5\text{Fe}^{3+} + \text{Mn}^{2+} + 4\text{H}_2\text{O}$. Given the concentrations of all are 0.1M , $Q = [0.1]^5 [0.1]^1 / [0.1]^5 [0.1]^1 [0.1]^8 = 10^8$. Thus using Nernst Equation,

$\Delta E = E_0 - 0.0591 / n \times \log Q = 0.74 \text{ V} - 0.0591 / 5 \times \log(8) = + 0.65 \text{ V}$ which is a galvanic cell.

69. The potentials for those options are (respectively) $524\text{mV} + 246 \text{ mV} = 770\text{mV}$, $39\text{mV} + 640 \text{ mV} = 679 \text{ mV}$, and 438 mV . The last option has the lowest reduction potential, which means it is least likely to be reduced, which means that is least likely to function as an oxidant.

70. a) $-0.111\text{V} + 0.197 \text{ V} = 0.086 \text{ V}$

b) $0.023\text{V} + 0.197 \text{ V} - 0.241 \text{ V} = -0.021 \text{ V}$

c) $-0.023 \text{ V} + 0.241 \text{ V} - 0.197 \text{ V} = 0.021 \text{ V}$
